

INVIDIA CORE

Power protection that disappears into the wall

Track 1 · Reimagining the Stabilizer for the Next Decade

V-Guard Big Idea Tech Design Contest 2026

**Every Indian home with a stabilizer has two boxes
doing one job, in the same place.**

TODAY

Two boxes. One job. Same wall.

It shows you the voltage is bad. It cannot fix it.

V-Guard already manufactures both halves — Invidia+ and VMT 500/1000 Plus.

THE PROPOSAL

Put the fixing inside the board.

MCB + RCCB + SPD + VOLTAGE CORRECTION
one enclosure · one DIN rail

Power protection stops being an appliance you buy, and becomes infrastructure the building already has.

WHY NOBODY HAS DONE IT

A whole-house transformer will not fit in a sealed box.

8,000 W
of iron and copper

Several kilograms. Runs hot.

Put that beside your MCBs and they overheat
and start tripping for no reason.

So the idea only works if the correction gets much smaller.

There are two ways. They stack.

SHRINK ONE

Fix circuits, not homes.

☒	Air conditioner	compressor
☒	Refrigerator	compressor
☐	Lights & fans	LED + BLDC — runs at 100–280 V
☐	Sockets	wide-range power supplies

One AC circuit is 3,000 W — not 8,000 W.

Only the distribution board can pick and choose. A plug-in unit does one appliance; a mainline unit must do everything.

SHRINK TWO

Don't rebuild the voltage. Top it up.

OLD WAY

SERIES INJECTION

Like water pressure.

A full pumping station takes all the water and re-pressurises it.

A booster pump in the pipe just adds the missing pressure.

Same result at the tap.

Far smaller machine.

Fifty volts instead of two-thirty — so about a fifth of the power.

PUT THEM TOGETHER

Ten times smaller.

Whole house, old method

8,000 W

kilograms of hot iron

Only the circuits that need it

3,000 W

less than half

Only the shortfall

~700 W

fits on a DIN rail

700 W with a small heatsink fits next to the MCBs. 8,000 W of iron never could.

INSIDE THE ENCLOSURE

Only the ways that need it.

SINGLE ENCLOSURE

Each module is sized to its own MCB — a 16 A MCB is a 16 A ceiling, so nothing you plug in can overload it.

If a module fails or overheats, a relay bypasses it: you lose the correction, never the power.

WHY IT IS A BETTER BUSINESS

**It stops being a purchase.
It becomes a specification.**

TODAY

Buy an AC → remember the stabilizer
→ compare five brands in a shop.
Low margin. You might buy a rival's.

WITH INVIDIA CORE

The electrician fits it while the house
is being wired. You were never in that
decision — and never compared price.

Nobody removes a distribution board to save Rs 1,500.

A channel V-Guard already owns through switchgear and wire. Revenue grew 7.0%; profit fell 1.7% — the problem is margin, not volume.

WHAT WE WILL NOT OVERCLAIM

The heat must be proven, not asserted.

The arithmetic says 700 W is manageable where 8,000 W was not.
But “should be” is not “is.”

TEST ONE

thermocouples inside a real enclosure, fully loaded, confirming the MCBs stay within rated temperature

If that test fails, the idea fails. That is why it is first.

Also honest: a board cannot see inside a circuit. If an AC shares a way with lights, it needs its own way — standard practice for heavy loads anyway. New construction and rewiring first; retrofit second.
